incomplete: may contain errors, run-ons, half-thoughts, etc.

## 0.1 INTRODUCTION

- Hemp (Cannabis sativa L.) is an annual crop with potential uses as a source of food or feed from grain, and bast fiber or hurd from the stalk. Hemp cultivars are com-
- $_{\rm 21}$   $\,$  monly grown for one or both purposes and a cultivar may be referred to as a grain,
- fiber, or dual-purpose type. Because of protein's nutritional importance, the protein
- content of a grain crop is an prime consideration for researchers, producers, and con-
- $_{24}$  sumers. Whole hemp grain typically contains approximately 20-30% protein (Bárta
- et al., 2024; Ely & Fike, 2022; callaway2004?). Crude protein (CP) is often used
- $_{\rm 26}$   $\,$  as a proxy for the direct measurement of protein concentration and consists of the
- multiplication of nitrogen concentration by a conversion factor because measuring
- $_{\rm 28}$   $\,$   $\,$  nitrogen concentration is relatively easy and cheap via laboratory assay (Hayes,
- 29 2020).

44

53

- Near-infrared spectroscopy (NIRS) technology is rapid, non-destructive, and cheap,
- and consists of the measurement of NIR radiation reflected from a sample (Roberts
- et al., 2004). NIR spectra from many samples are related to laboratory values for
- components such as moisture, protein, fat, or fiber (Roberts et al., 2004). NIRS
- technology has been used since the 1970's to assess forage CP (Reeves, 2012;
- Williams, 1975). A NIRS calibration set often consists of samples from one species
- grown in many environments encompassing the range of expected values from the
- analyte or analytes (Chadalavada et al., 2022). Partial least squares regression
- (PLSR) is a typical method used in the agricultural and food sciences to relate spec-
- tra to analyte (Roberts et al., 2004). PLSR calculates principal components (PCs)
- which relate to the dependent variable and summarize the spectra and uses a subset
- of PCs in order to fit the regression model. PLSR is commonly used in spectroscopy
- $_{42}$  because it tends to work well with highly-correlated spectral data. Typically the
- number of principal components is chosen via cross-validation to avoid overfitting.

#### CITES FOR ALL OF THIS

- 45 A NIRS-scanned sample of undamaged grain may used for other purposes or it may
- planted as a seed. In wheat and corn, grain protein content has been shown to be
- heritable (Geyer et al., 2022; Giancaspro et al., 2019). This suggests (at least poten-
- $_{48}$  tially) that NIRS technology could serve as resource to more rapidly identify high
- 49 CP hemp germplasm, enabling the delivery of higher CP hemp grain cultivars faster.
- 50 For this study, a benchtop NIR spectrometer was used to develop a model to predict
- 51 CP content based on a data set of hemp grain representing multiple years, locations,
- and cultivars from grain and dual-purpose hemp types using PLSR.

Spectral data were obtained from whole (unground) hemp grain samples, harvested 57 at maturity, collected from 2017 - 2021 from 18 cultivar trials in New York (NY) 58 (NA samples). Grain samples were obtained by hand sampling or mechanical harvest and were cleaned of chaff and dried at 30 C for six days in a forced-air dryer. 60 In total, 38 cultivars were represented in the data set. Cultivars were grain or dual-61 purpose types and included both commercially available and experimental material. 62

All cultivar trials were planted in randomized complete block design with each cultivar replicated four times. The 2017 data were comprised of samples from the same thirteen cultivars sampled from six NY locations. For those trials, grain was har-65 vested from each plot individually and aggregated by cultivar within each trial. Four 66 subsamples were drawn from each aggregated sample and scanned separately. These spectra were averaged at each 2 nm increment. All remaining samples from 2018-68 2021 were collected on a per-plot basis. All possible cultivars and possible locations 69 were represented in 2017, but only a selected subset of cultivars and locations were 70 represented in 2018-2021. 71

## 0.2.2 Spectral Data Collection and Preprocessing

A benchtop NIR spectrometer (FOSS/ NIR FOSS/ NIR Systems model 5000) was used to obtain the spectra (FOSS North America, Eden Prairie, MN, USA). Spectra were collected every 2 nm from 1100-2498 nm and the logarithm of reciprocal reflectance was recorded.

WINISI software version 1.02A (Infrasoft International, Port Matilda, PA, USA) was 77 used to average the spectra in 2017, as well as to select samples for laboratory assay. Samples were selected according to their spectral distance from their nearest neighbor within the calibration data set with a cutoff of a distance of 0.6 H, where H is 80 approximately equal to the squared Mahalanobis distance divided by the number of principal components used in the calculation (Garrido-Varo et al., 2019). Prior 82 to selection selection, spectra were preprocessed using SNV-detrend with settings 1,4,4,1 for the derivative, gap, smooth, and smooth 2 settings respectively.

## 0.2.3 Laboratory Validation

Laboratory assays were performed by Dairy One Forage Laboratory (Ithaca, NY). 86 For those assays, 1mm ground samples were analyzed by combustion using a CN628 or CN928 Carbon/Nitrogen Determinator. Samples from 2017 were aggregated as 88 described above, but the remaining samples were not aggregated. 89

## 0.2.4 Model Development

Calibration and validations sets were created by dividing the laboratory CP values 91 into tertiles according to their percent CP in order to ensure that the range of CP 92 values was present in both calibration and validation sets. Within each tertile, 75% 93 of the samples were randomly assigned to the calibration set and the remaining 25%were assigned to the validation set. For each calibration set, models were developed in caret using PLSR. In fitting the model, the number of principal components was optimized over au grid search from 1-20. Model performance was evaluated with 25 iterations of bootstrapping and minimized root mean squared error (RMSE) in 98 selecting the number of principal components in the final model.

## Source: Article Notebook

Initially a number of common spectral preprocessing methods were tested by creating 100 calibration and validation sets as described above. Spectral data from those data sets were transformed by each of the following methods: 1) first derivative, 2) Savitzky-Golay (SG) using the first derivative, third order polynomial, and a window of size 5, 3) gap-segment derivative using the first derivative, a gap of eleven, and a segment size of 5, 4) standard normal variate (SNV), 4) standard normal variate following Savitzky-Golay (SNV-SG) (same SG parameters as above), 5) SNV-detrend with second order polynomial, and 6) multiplicative scatter correction.

For each of these preprocessing methods, models were fit and predictions were made 109 on the corresponding validation set (since there were 8 preprocessing methods, 8 110 separate models were fit for each of the 100 sets. The relationship between the pre-111 dicted and actual values of the validation set were calculated via RMSE, R<sup>2</sup> and 112 Ratio of Performance to InterQuartile distance (RPIQ), three common model as-113 sessment metrics. Larger R<sup>2</sup> and RPIQ, and smaller RMSE values are superior. 114 Analyses of variance (ANOVA) were performed for each of these metrics in order to 115 compare the preprocessing methods. For each ANOVA, each data set was considered 116 as a subject and allowing different variances for each preprocessing method.

Once the most promising preprocessing method was identified, 1000 more data sets were created and analyzed via that method and performance on the validation sets was summarized with RMSE, R<sup>2</sup>, and RPIQ.

## 0.2.5 Additional software used

We used R version 4.3.3 (R Core Team, 2024) and the following R packages: caret v. 6.0.94 (Kuhn & Max, 2008), data.table v. 1.15.2 (Barrett et al., 2024), emmeans v. 1.10.0 (Lenth, 2024), nlme v. 3.1.163 (J. Pinheiro et al., 2023; J. C. Pinheiro & Bates, 2000), pls v. 2.8.3 (Liland et al., 2023), prospectr v. 0.2.7 (Stevens & Ramirez-Lopez, 2024), skimr v. 2.1.5 (Waring et al., 2022), tidymodels v. 1.1.1 (Kuhn & Wickham, 2020), tidyverse v. 2.0.0 (Wickham et al., 2019).

## 0.3 RESULTS AND DISCUSSION

## 0.3.1 Laboratory assay CP values

Laboratory assay percent CP values are summarized in the following table. These are similar to the range of CP values observed in the literature, indicating an reasonable basis for a chemometric model. The CP values are left-skewed and two thirds of the samples contained more than 25% CP.

Table 1: Summary of Laboratory Assayed CP Values (Percent Dry Matter)

Mean	Sd	Minimum	First Quartile	Median	Third Quartile	Maximum
26.1	2.5	20.8	23.9	26.4	28.2	30.8

## 0.3.2 Preprocessing methods comparison

Source: Article Notebook

Source: Article Notebook
All preprocessing methods outperformed raw spectral data Table 2. Averaged together, all preprocessed spectra were superior to raw spectra, with lower RMSE, and higher  $R^2$  and RPIQ values (significant at  $\alpha$  level <0.001). Preprocessing methods had -11.6 % lower RMSE, and had 3.1% higher  $R^2$  7.4% higher RPIQ than unprocessed spectra.

The SNV-SG method had the lowest RMSE, highest  $R^2$ , and highest RPIQ averaging over all iterations. SNV-SG RMSE averaged 1.4% lower, while  $R^2$  and RPIQ averaged 0.4% and 2.4% higher respectively than the next best preprocessing method (SG in both cases), but the difference between the best and second best method by metric were only statistically significant at  $\alpha < 0.05$  for RPIQ. RPIQ was devised to accurately reflect the spread of data in skewed populations (bellon-maurel2010?) and thus offers a robust metric for model assessment in this context, where the CP data are skewed. Therefore the superiority of SNV-SG as measured via RPIQ made it the best choice for the final model.

Table 2: Evaluation of Preprocessing Methods by Metric  $\pm$  Standard Error

SNV and SNV-detrend correct light scatter. SG is a smoothing filter that regresses on the signal over a series of windows. Derivatives remove noise, but not necessarily light scattering. **cite** 

cite: Barnes RJ, Dhanoa MS, Lister SJ. 1989. Standard normal variate transformation and de-trending of near-infrared diffuse reflectance spectra. Applied spectroscopy, 43(5): 772-777.

The preprocessing methods examined represent a portion of those available. As well, preprocessing methods tend to have a number of user-adjustable parameters whose various permutations were not tested. This subset of preprocessing methods and parameters nonetheless contained substantial variations in model quality, demonstrating the importance of the selection of an appropriate preprocessing method.

## 0.3.3 Final model development and summary

Source: Article Notebook

The model improved most rapidly as the number of principal components increased from 1 to 7, with the inclusion of each additional PC being associated with a decrease in RMSE of 5-12%. From 8 to 12 PCs, model performance continued to improve, although gains were more modest (decrease in RMSE of 0.7-3%). With 13 or more PCs, performance gains were minimal and the relative ranks of the models tended to be stable Figure 1.

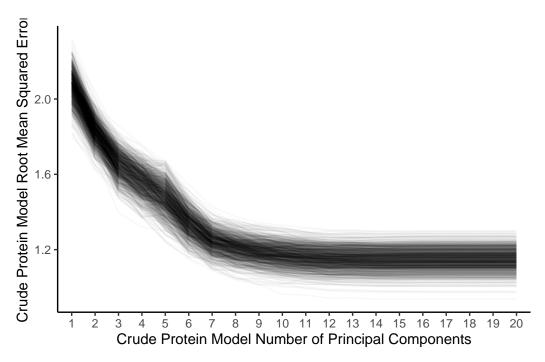

Figure 1: Decreasing RMSE with increasing number of PCs

177

179

180

181

182

183

178 Source: Article Notebook

Final model performance was similar, but not identical to, that obtained during the initial comparison of preprocessing methods. The final models' mean RMSE was 1.03,  $R^2$  was 0.83, and RPIQ was 3.89 (all calculated on the test sets). Despite the generally good model performance, a subset of poor models can be seen. For example, Figure 2 shows twenty-one models with  $R^2$  below 0.7. more comment on poor models?

This study is limited in that it represents the creation of one model based upon spectra collected from one machine. NIRS calibrations can be unique to a particular machine, even if the machines compared are of the same model ( ${\bf Reeves\_2012?}$ ). As well, the calibration and validation sets are relatively small.

This research showed the promise of the use of NIRS in order to make predictions concerning %CP in hemp grain using PLS. Promising preprocessing methods were identified and a model was validated. Further research could refine the model by including more samples or by examining other predictive methods.

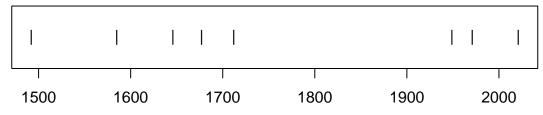

Figure 4: Timeline of recent earthquakes on La Palma

- 340 Source: Article Notebook
- 341 Source: Article Notebook
- Based on data up to and including 1971, eruptions on La Palma happen every 79.8
- years on average.
- Studies of the magma systems feeding the volcano, such as (marrero2019?), have
- proposed that there are two main magma reservoirs feeding the Cumbre Vieja vol-
- cano; one in the mantle (30-40km depth) which charges and in turn feeds a shal-
- lower crustal reservoir (10-20km depth).
- Eight eruptions have been recorded since the late 1400s (Figure 4).
- Data and methods are discussed in Section 0.9.
- Let x denote the number of eruptions in a year. Then, x can be modeled by a Poisson distribution

$$p(x) = \frac{e^{-\lambda} \lambda^x}{x!} \tag{1}$$

where  $\lambda$  is the rate of eruptions per year. Using Equation 1, the probability of an eruption in the next t years can be calculated.

Table 4: Recent historic eruptions on La Palma

Name	Year
Current	2021
Teneguía	1971
Nambroque	1949
El Charco	1712
Volcán San Antonio	1677
Volcán San Martin	1646
Tajuya near El Paso	1585
Montaña Quemada	1492

Table 4 summarises the eruptions recorded since the colonization of the islands by Europeans in the late 1400s.

La Palma is one of the west most islands in the Volcanic Archipelago of the Canary Islands (Figure 5).
